at/IN each/DT other/JJ ,/, why/WRB there/EX you/PRP
are/VBP indeed/RB ./.

Among easiest of NLP problems

- **State-of-the-art methods achieve ~97% accuracy.**
- **Simple heuristics can go a long way.**
 - ~90% accuracy just by choosing the most frequent tag for a word (MLE)
 - To improve reliability: *need to use some of the local context.*
- **But defining the rules for special cases can be time-consuming, difficult, and prone to errors and omissions**

Approaches

1. **rule-based:** involve a large database of hand-written disambiguation rules, e.g. that specify that an ambiguous word is a noun rather than a verb if it follows a determiner.
2. **probabilistic:** resolve tagging ambiguities by using a training corpus to compute the probability of a given word having a given tag in a given context.
 - HMM tagger
3. **hybrid corpus-/rule-based:** E.g. transformation-based tagger (Brill tagger); learns symbolic rules based on a corpus.
4. **ensemble methods:** combine the results of multiple taggers.

Transformation-based learning

- **Supervised machine learning technique**
 - For acquiring simple default heuristics and rules for special cases
 - Rules are learned by iteratively collecting errors and generating rules to correct them.
- **Requires a large (training) corpus of manually tagged text**

TBL: high-level algorithm

Learns an ordered list of transformations (i.e. rewrite rules)

Rewrite rules

- **Rule**
 - Change *modal* to *noun*, if preceding word is a *determiner*
- **Example**
 - Determiner: the, a, an, this, that ...
 - Modals: can, will, should, would, may, might...followed by the main verb
 - The/*det* can/*modal* rusted/*verb* ./.
 - The/*det* can/*noun* rusted/*verb* ./.

Transformation-based learning

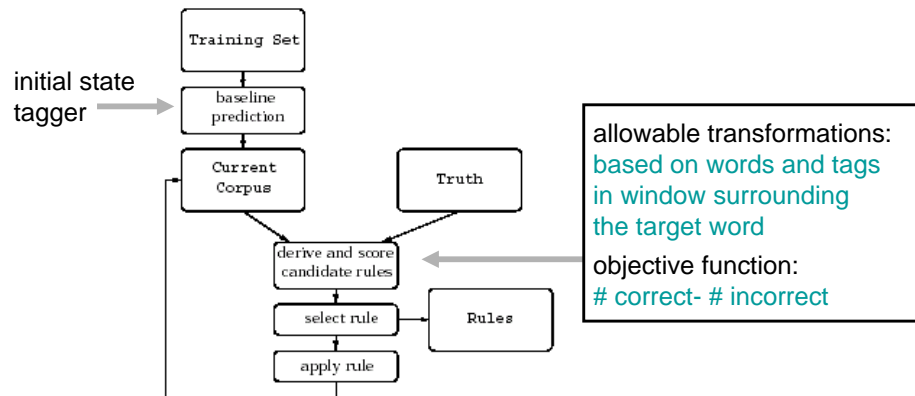

Figure 1: Transformation-based Learning

[Brill 1993]

Learning algorithm: greedy search

- **Specify**
 - An initial state annotator
 - Space of allowable transformations
 - Objective function for comparing corpus to truth
- **Algorithm**
 - Iterate
 - Try each possible transformation
 - Choose the one with the best score
 - Add to list of transformations
 - Update the training corpus
 - Until no transformation improves performance

Transformation templates

- **Change tag A to B when:**
 - preceding/following word is tagged Z
 - word two before/after is tagged Z
 - one of the two preceding/following words is tagged Z
 - one of the three preceding/following words is tagged Z
 - preceding word is tagged Z and following word is tagged W
 - preceding/following word is tagged Z and word two before/after is tagged W

Generating transformations

- Apply the initial tagger and compile types of tagging errors. Each type of error is of the form:
 - <incorrect tag, desired tag, # of occurrences>
- For each error type, instantiate all templates to generate candidate transformations.
- Apply each candidate transformation to the corpus and count the number of corrections and errors that it produces. Save the transformation that yields the greatest improvement.
- Stop when no transformation can reduce the error rate by a predetermined threshold.

Example

- Suppose that the initial tagger mistags 159 words as verbs when they should have been nouns.
- Produces the error triple:
< verb, noun, 159 >
- Suppose template #3 is instantiated as the rule:
Change the tag from verb to noun if one of the two preceding words is tagged as a determiner.
- When this template is applied to the corpus, it corrects 98 of the 159 errors. But it also creates 18 new errors. Error reduction is $98 - 18 = 80$.

Learned rules

1. **NN→VB** if the previous tag is **TO**
I wanted to/TO win/NN→VB a Subaru WRX...
2. **VBP→VB** if one of the prev-3 tags is **MD**
The food might/MD vanish/VBP→VB from sight.
3. **NN→VB** if one of prev-2 tags is **MD**
I might/MD not reply/NN→VB
4. **VB→NN** if one of the prev-2 tags is **DT**
5. **VBD→VBN** if one of the prev-3 tags is **VBZ**
6. **VBN→VBD** if one of the previous tag is **PRP**

Tagging new text

- **The resulting tagger consists of two phases:**
 - Use the initial tagger to tag all the text
 - Apply each transformation, in order, to the corpus to correct some of the errors.
- **The order of the transformations is very important!**
 - For example, it is possible for a word's tag to change several times as different transformations are applied. In fact, a word's tag could thrash back and forth between the same two tags.

Evaluation

- **Training: 600,000 words from the Penn Treebank WSJ corpus**
- **Testing: separate 150,000 words from PTB**
- **Assumes all possible tags for all test set words are known.**
- **97.0% accuracy**
- **Tagger learned 378 rules.**

Problems?

- **Not lexicalized**
 - Transformations are entirely tag-based; no specific words were used in the rules.
 - But certain phrases and lexicalized expressions can yield idiosyncratic tag sequences, so allowing the rules to look for specific words should help...
 - Add additional templates
 - E.g. when the preceding/following word is *w...*
 - Tagger achieves 97.2% accuracy
 - First 200 rules achieved 97.0%
 - First 100 rules achieved 96.8%
 - Learns 447 rules
- **Unknown words**

Transformation-based learning

- **Part-of-speech tagging**
[Brill 1995; Ramshaw & Marcus 1994]
- **Prepositional phrase attachment**
[Brill & Resnik 1995]
- **Syntactic parsing**
[Brill 1994]
- **Noun phrase chunking**
[Ramshaw & Marcus 1995, 1999]
- **Context-sensitive spelling correction**
[Mangu & Brill 1997]
- **Dialogue act tagging**
[Samuel et al. 1998]
