Assignment 4

- Should be working on it now
 - Tasks 1-3 by Friday
 - Task 4 by Monday
 - Task 5 by Wednesday

Dictionaries

Key-Value Pairs

- The last built-in type: dictionary (or dict)
 - One of the most important in all of Python
 - Like a list, but built of key-value pairs
- Keys: Unique identifiers
 - Think social security number
 - At Cornell we have netids: jrs1
- Values: Non-unique Python values
 - John Smith (class '13) is jrs1
 - John Smith (class '16) is jrs2

Idea: Lookup values by keys

Basic Syntax

- Create with format: {k1:v1, k2:v2, ...}
 - Both keys and values must exist
 - Ex: d={'jrs1':'John','jrs2':'John','wmw2':'Walker'}
- Keys must be non-mutable
 - ints, floats, bools, strings, tuples
 - Not lists or custom objects
 - Changing a key's contents hurts lookup
- Values can be anything

Using Dictionaries (Type dict)

- Access elts. like a list
 - d['jrs1'] evals to 'John'
 - d['jrs2'] does too
 - d['wmw2'] evals to 'Walker'
 - d['abc1'] is an error
- Can test if a key exists
 - 'jrs1' in d evals to True
 - 'abcl' in d evals to False
- But cannot slice ranges!

Dictionaries Can be Modified

- Can reassign values
 - d['jrs1'] = 'Jane'
 - Very similar to lists
- Can add new keys
 - d['aaa1'] = 'Allen'
 - Do not think of order
- Can delete keys
 - del d['wmw2']
 - Deletes both key, value

Dictionaries Can be Modified

- Can reassign values
 - d['jrs1'] = 'Jane'
 - Very similar to lists
- Can add new keys
 - d['aaa1'] = 'Allen'
 - Do not think of order
- Can delete keys
 - del d['wmw2']
 - Deletes both key, value

Dictionaries Can be Modified

- Can reassign volues
 - d['jrs1'] Change key = Delete + Add jrs2':'John',
 will we wanter'}
 - Very similar to lists
- Can add new keys
 - d['aaa1'] = 'Allen'
 - Do not think of order
- Can delete keys
 - del d['wmw2']
 - Deletes both key, value

Dicts vs Objects

- Can add new variables
- Does not check bounds of the content variables
- Variables fixed (sort-of)
- Possibly checks bounds of the content variables

Dicts vs Objects

- Can add new variables
- Does not check bounds of the content variables
- Variables fixed (sort-of)
- Possibly checks bounds of the content variables

Dictionaries: Iterable, but not Sliceable

- Can loop over a dict
 - Only gives you the keys
 - Use key to access value

for k in d:

Loops over keys
print(k) # key
print(d[k]) # value

- Can iterate over values
 - Method: d.values()
 - But no way to get key
 - Values are not unique

To loop over values only
for v in d.values():
 print(v) # value

Other Iterator Methods

- Keys: d.keys()
 - Sames a normal loop
 - Good for *extraction*
 - keys = list(d.keys())
- Items: d.items()
 - Gives key-value pairs
 - Elements are tuples
 - Specialized uses

for k in d.keys():
 # Loops over keys
 print(k) # key
 print(d[k]) # value

for pair in d.items():
 print(pair[0]) # key
 print(pair[1]) # value

Other Iterator Methods

Dictionaries and Fruitful Functions

- Dictionaries handled similar to lists
 - Go over dictionary (keys) with *for-loop*
 - Use *accumulator* to gather the results
- Only difference is how to access value
 - Remember, loop variable is keys
 - Use **keys** to access the **values**
 - But otherwise the same

Dictionary Loop with Accumulator

def max_grade(grades):

```
"""Returns max grade in the grade dictionary
```

Precondition: grades has netids as keys, ints as values""" maximum = 0 # Accumulator

For each student

if student grade exceeds maximum

make that grade the new maximum

return maximum

Dictionary Loop with Accumulator

```
def max_grade(grades):
```

return maximum

Another Example

def netids_above_cutoff(grades,cutoff):

"""Returns list of netids with grades above or equal cutoff

Precondition: grades has netids as keys, ints as values.

cutoff is an int."""

result = [] # Accumulator

For each student

if student's grade is above cutoff
 # add student to the result

return result

Another Example

def netids_above_cutoff(grades,cutoff):

```
"""Returns list of netids with grades above or equal cutoff
```

```
Precondition: grades has netids as keys, ints as values.
```

cutoff is an int."""

```
result = [] # Accumulator
```

```
for k in grades:
```

```
if grades[k] >= cutoff:
    result.append(k)
```

Add key to the list result

return result

Dictionaries and Mutable Functions

- Restrictions are different than list
 - Okay to loop over dictionary to change
 - You are looping over *keys*, not *values*
 - Like looping over positions
- But you may not add or remove keys!
 - Any attempt to do this will fail
 - Have to create a key list if you want this

A Subtle Difference

But This is Okay

def add_bonus(grades,bonus):

```
"""Gives bonus points to everyone in grades
```

Precondition: grades has netids as keys, ints as values.

bonus is an int."""

No accumulator. This is a procedure

for student in grades:

Modifies the dictionary, but does not change keys
grades[student] = grades[student]+bonus

Another Example

def merge(dict1,dict2):

"""Updates dict1 to include the contents of dict2.

If a key is already in dict1, then assign the max of dict1, dict2

Precondition: dict1, dict2 have str as keys, int as values.""" for key in dict2:

Looping over dict2; safe to modify dict1

```
if key in dict1:
```

```
dict1[key] = max(dict1[key],dict2[key])
```

else:

```
dict1[key] = dict2[key]
```

Nesting Dictionaries

- Remember, values can be anything
 Only restrictions are on the keys
- Values can be lists (Visualizer)

• $d = \{ 'a': [1,2], 'b': [3,4] \}$

• Values can be other dicts (Visualizer)

• $d = \{ 'a': \{ 'c':1, 'd':2 \}, 'b': \{ 'e':3, 'f':4 \} \}$

• Access rules similar to nested lists

Example: d['a']['d'] = 10

Example: JSON File

- **JSON:** File w/ Python dict
 - Actually, minor differences
- weather.json:
 - Weather measurements at Ithaca Airport (2017)
 - Keys: Times (Each hour)
 - Values: Weather readings
- This is a *nested* JSON
 - Values are also dictionaries
 - Containing more dictionaries
 - And also containing lists

JSONs vs Dictionaries

- JSONs *look* like dictionaries, but are not same
 - JSONs are strings (to send over internet)
 - Dictionaries are a type with its own operations
- But you can go back and forth between them
 >> import json # The json module in Python
 >> d = json.loads(s) # Converts JSON s to dict d
 >> s = json.dumps(d) # Converts dict d to JSON s
- So we often think of the two as the same
 - JSON is to dict as CSV is to nested lists

Navigating this File

```
"wind" : {
  "speed" : 13.0,
  "crosswind" : 5.0
  },
"sky" : [
     "cover" : "clouds",
     "type" : "broken",
     "height" : 1200.0
  },
                   Access this
     "type" : "
                      value
     "height" : \....
```

- Let **d** be the dict to left
- Need to access a value
- How do we do it?

A: d['height'] B: d['height']['sky'] C: d['sky']['height'] D: d['sky'][0]['height'] E: I don't know

Navigating this File

- Let **d** be the dict to left
- Need to access a value
- How do we do it?

```
A: d['height']
B: d['height']['sky']
C: d['sky']['height']
D: d['sky'][0]['height']
E: I don't know
```

Dictionaries and Recursion

- Dictionaries are **not sliceable**
 - Makes it difficult to do divide and conquer
 - So rare to be used in recursion by itself
 - Often the *answer* to a recursion, not the *input*
- However, the **key list** is sliceable
 - Can recurse on key list, not the dict
 - This requires a helper function
 - Helper is recursive, not the main function

def max_grade(grades):

```
"""Returns max grade in the grade dictionary
```

Precondition: grades has netids as keys, ints as values"""

```
# WE CANNOT SLICE A DICTIONARY
# We need to pull out keys and use a recursive helper
netids = list(grades.keys())
```

return max_grade_helper(netids,grades)

def max_grade_helper(netids,grades):

```
"""Returns max grade among given netids
```

Precond: netids a list of keys in grades, grades a dict w/ int values""" # Process small data

```
if len(netids) <= 1:</pre>
```

return grades[netids[0]] if len(netids) == 1 else 0

Break it up into left and right

Combine the answers

def max_grade_helper(netids,grades):

```
"""Returns max grade among given netids
```

```
Precond: netids a list of keys in grades, grades a dict w/ int values"""
# Process small data
```

```
if len(netids) <= 1:</pre>
```

return grades[netids[0]] if len(netids) == 1 else 0

Break it up into left and right

```
left = grades[netids[0]]
```

right = max_grade_helper(netids[1:],grades)

Combine the answers

def max_grade_helper(netids,grades):

```
"""Returns max grade among given netids
```

```
Precond: netids a list of keys in grades, grades a dict w/ int values"""
# Process small data
```

```
if len(netids) <= 1:</pre>
```

return grades[netids[0]] if len(netids) == 1 else 0

Break it up into left and right

left = grades[netids[0]]

right = max_grade_helper(netids[1:],grades)

Combine the answers

```
return max(left,right)
```
