Lecture 19

Using Classes Effectively

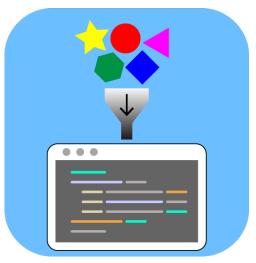

Announcements for Today

Assignments

- A4 is due **Thursday** night
 - Survey is still open
- A5 to be posted **tomorrow**
 - Short written assignment
 - Due next Thursday
- A6 also posted **tomorrow**
 - Due November 15th
 - Follow the microdeadlines!
 - Get started on it first

Optional Videos

- Videos 20.9-20.10 today
- Also Lesson 21 for today
- Lesson 22 for next time

Recall: The __init__ Method

w – worker (opama', 1234, None)

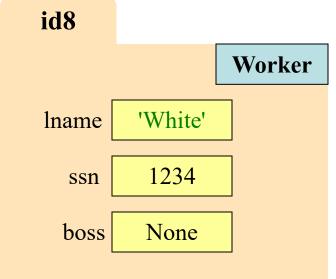

def___init___(self, n, s, b):

"""Initializer: creates a Worker

Has last name n, SSN s, and boss b

```
Precondition: n a string,
s an int in range 0..9999999999,
b either a Worker or None. """
self.lname = n
self.ssn = s
```

Called by the constructor

self.boss = b

Recall: The __init__ Method

two underscores w – worker(opama', 1234, None)

```
def init (self, n, s, b):
```

"""Initializer: creates a Worker

```
Has last name n, SSN s, and boss \boldsymbol{b}
```

```
Precondition: n a string,
s an int in range 0..9999999999,
b either a Worker or None. """
self.lname = n
self.ssn = s
```

Are there other special methods that we can use?

```
self.boss = b
```

Example: Converting Values to Strings

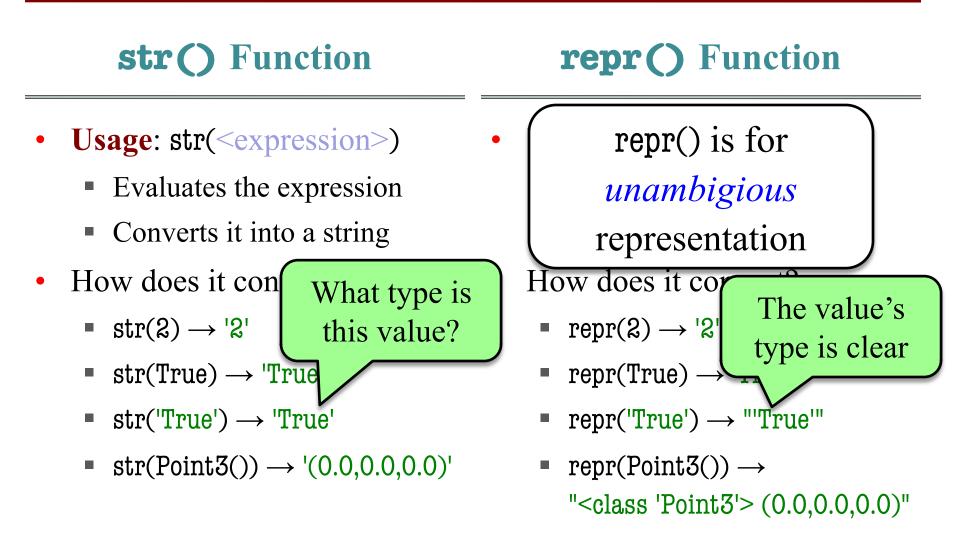

str() Function

- **Usage**: str(<expression>)
 - Evaluates the expression
 - Converts it into a string
- How does it convert?
 - $str(2) \rightarrow '2'$
 - $str(True) \rightarrow 'True'$
 - $str('True') \rightarrow 'True'$
 - $str(Point3()) \rightarrow (0.0, 0.0, 0.0)'$

repr() Function

- **Usage:** repr(<expression>)
 - Evaluates the expression
 - Converts it into a string
- How does it convert?
 - repr(2) \rightarrow '2'
 - repr(True) \rightarrow 'True'
 - repr('True') \rightarrow "'True'"
 - repr(Point3()) →
 "<class 'Point3'> (0.0,0.0,0.0)"

Example: Converting Values to Strings

What Does str() Do On Objects?

- Must add a special method
 - str_ for str()
 - repr_ for repr()
- Could get away with just one
 - repr() requires __repr__
 - str() can use <u>repr</u>
 (if <u>str</u> is not there)

```
class Point3(object):
   """Class for points in 3d space"""
   def str (self):
      """Returns: string with contents"""
      return '('+str(self.x) + ',' +
                str(self.y) + ',' +
                str(self.z) + ')'
   def __repr__(self):
      """Returns: unambiguous string"""
      return str(self. class )+
             str(self)
```

10/31/24

What Does str() Do On Objects?

- Must add a special method
 - str_ for str()
 - repr_ for repr()
- Could get away with just one
 - repr() requires __repr__
 - str() can use <u>repr</u>
 (if <u>str</u> is not there)

```
class Point3(object):
   """Class for points in 3d space"""
   def str (self):
     """Returns: string with contents"""
     return '('+str(self.x) + ',' +
                str(self.y) + ',' +
                str(self.z) + ')'
                          Gives the
   def __repr__(self):
                          class name
     """Returns: unambig
     return str(self.__class__)+
            str(self)
                           _repr___using
                                as helper
                          str
```

Using Classes Effectively

```
class Example(object):
  """A simple class"""
  def __init__(self,x):
     self.x = x
  def _____(self):
     return 'Value '+str(self.x)
  def __repr__(self):
     return 'Example['+str(x)+']'
```

```
>> a = Example(3)
```

>>> str(a) # a.___str()__

What is the result?

- A: '3'
- B: 'Value 3'
- C: 'Example[3]'

D: Error

E: I don't know

```
class Example(object):
  """A simple class"""
  def __init__(self,x):
     self.x = x
  def _____(self):
     return 'Value '+str(self.x)
  def __repr__(self):
     return 'Example['+str(x)+']'
```

>> a = Example(3)

>>> str(a)

What is the result?

A: '3'

B: 'Value 3'

C: 'Example[3]'

D: Error

E: I don't know

```
class Example(object):
  """A simple class"""
  def __init__(self,x):
     self.x = x
  def _____(self):
     return 'Value '+str(self.x)
  def __repr__(self):
     return 'Example['+str(x)+']'
```

>> a = Example(3)

>>> repr(a)

What is the result?

- A: '3'
- B: 'Value 3'
- C: 'Example[3]'
- D: Error
- E: I don't know

```
class Example(object):
  """A simple class"""
  def __init__(self,x):
     self.x = x
  def _____(self):
     return 'Value '+str(self.x)
  def __repr__(self):
     return 'Example['+str(x)+']'
                        No self
```

>> a = Example(3)

>>> repr(a)

What is the result?

- A: '3'
- B: 'Value 3'
- C: 'Example[3]'

D: Error

E: I don't know

Designing Types

From first day of class!

- **Type:** set of values and the operations on them
 - int: (set: integers; ops: +, -, *, //, ...)
 - Time (set: times of day; ops: time span, before/after, ...)
 - Worker (set: all possible workers; ops: hire,pay,promote,...)
 - Rectangle (set: all axis-aligned rectangles in 2D; ops: contains, intersect, ...)
- To define a class, think of a *real type* you want to make
 - Python gives you the tools, but does not do it for you
 - Physically, any object can take on any value
 - Discipline is required to get what you want

Making a Class into a Type

- 1. Think about what values you want in the set
 - What are the attributes? What values can they have?
- 2. Think about what operations you want
 - This often influences the previous question
- To make (1) precise: write a *class invariant*
 - Statement we promise to keep true **after every method call**
- To make (2) precise: write *method specifications*
 - Statement of what method does/what it expects (preconditions)
- Write your code to make these statements true!

class Time(object):
 """Class to represent times of day.

```
Inv: hour is an int in 0..23
Inv: min is an int in 0..59"""
```

```
def __init__(self, hour, min):
"""The time hour:min.
Pre: hour in 0..23; min in 0..59"""
```

```
def increment(self, hours, mins):
    """Move time hours and mins
    into the future.
    Pre: hours int >= 0; mins in 0..59"""
```

def isPM(self):

```
"""Returns: True if noon or later."""
```

Class Invariant

States what attributes are present and what values they can have.

A statement that will always be true of any Time instance.

Method Specification

States what the method does.

```
Gives preconditions stating what is assumed true of the arguments.
```

class Rectangle(object):
 """Class to represent rectangular region
 Inv: t (top edge) is a float
 Inv: l (left edge) is a float

Inv: b (bottom edge) is a float Inv: r (right edge) is a float Additional Inv: l <= r and b <= t."""

def __init__(self, t, l, b, r):
 """The rectangle [l, r] x [t, b]
 Pre: args are floats; l <= r; b <= t"""</pre>

def area(self):

"""Return: area of the rectangle."""

def intersection(self, other):
 """Return: new Rectangle describing
 intersection of self with other."""

Class Invariant

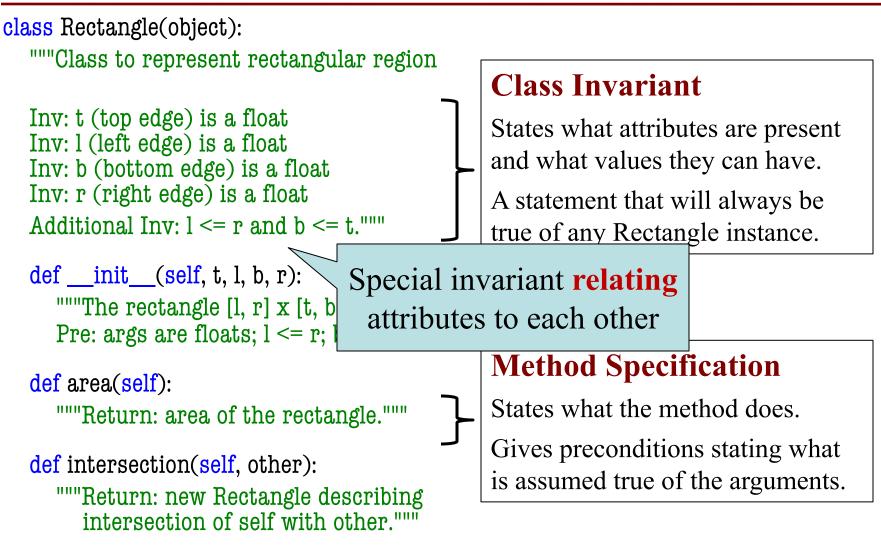

States what attributes are present and what values they can have.

A statement that will always be true of any Rectangle instance.

Method Specification

States what the method does.

Gives preconditions stating what is assumed true of the arguments.

class Hand(object):
 """Instances represent a hand in cards.

Inv: cards is a list of Card objects. This list is sorted according to the ordering defined by the Card class."""

def __init__(self, deck, n):
 """Draw a hand of n cards.
 Pre: deck is a list of >= n cards"""

def isFullHouse(self):
 """Return: True if this hand is a full
 house; False otherwise"""

def discard(self, k):
 """Discard the k-th card."""

Class Invariant

States what attributes are present and what values they can have.

A statement that will always be true of any Rectangle instance.

Method Specification

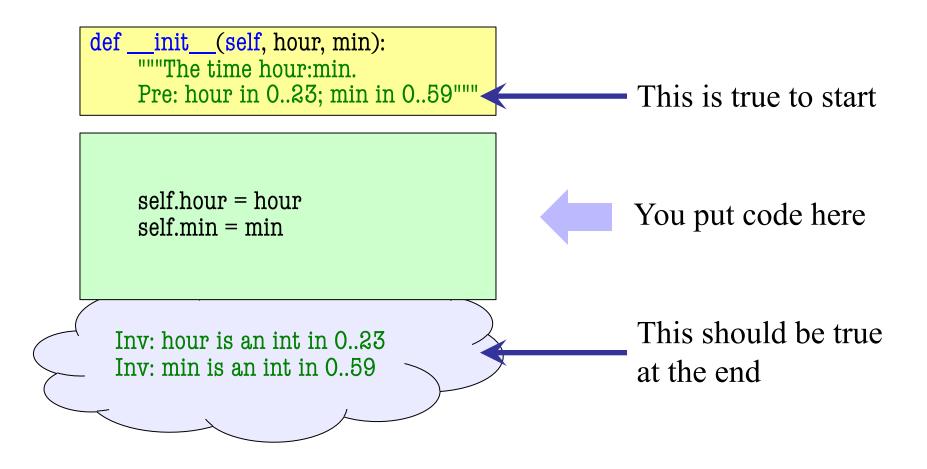

States what the method does.

Gives preconditions stating what is assumed true of the arguments.

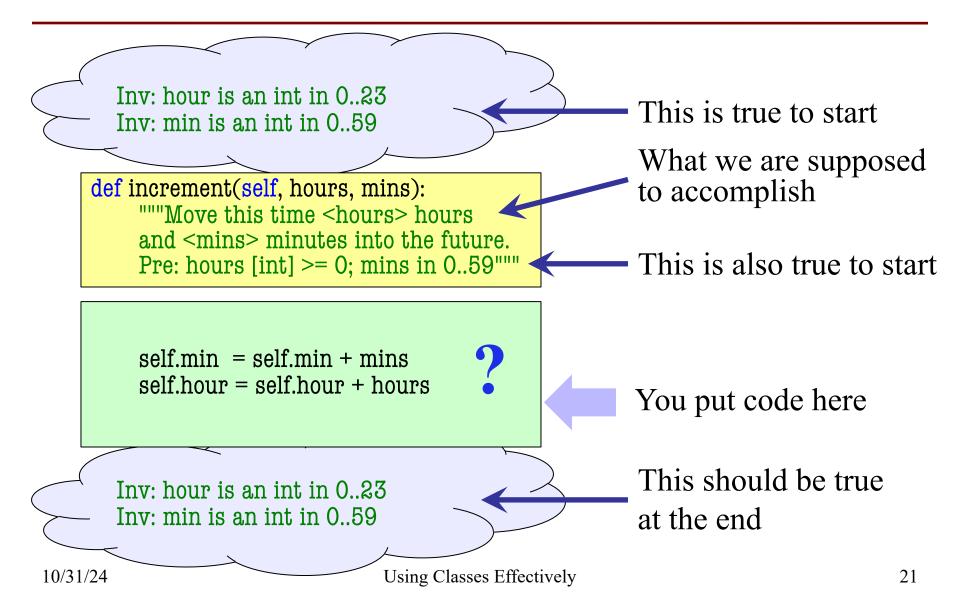

Implementing a Class

- All that remains is to fill in the methods. (All?!)
- When implementing methods:
 - 1. Assume preconditions are true
 - 2. Assume class invariant is true to start
 - 3. Ensure method specification is fulfilled
 - 4. Ensure class invariant is true when done
- Later, when **using the class**:
 - When calling methods, ensure preconditions are true
 - If attributes are altered, ensure class invariant is true

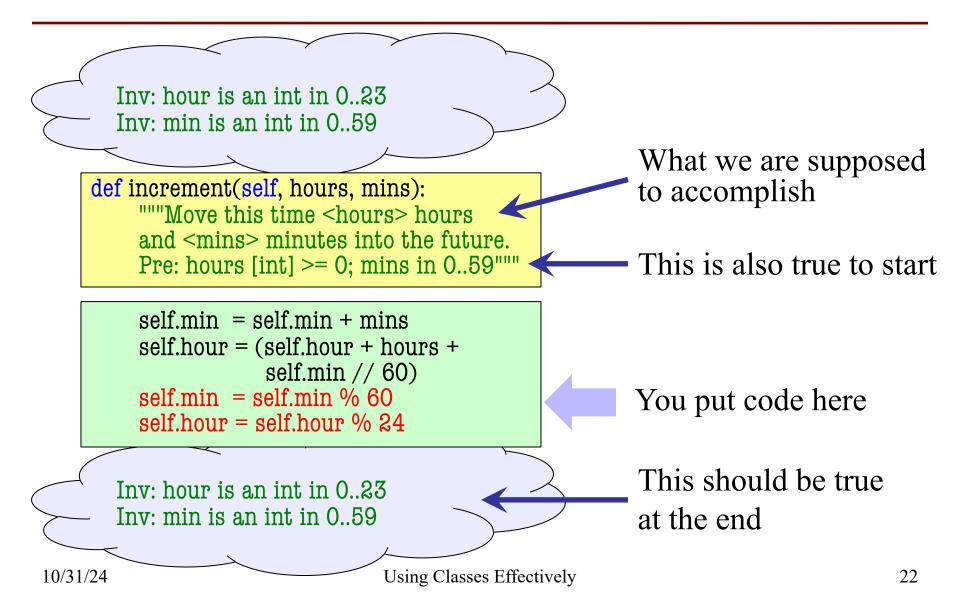

Implementing an Initializer

Implementing a Method

Implementing a Method

Object Oriented Design

Interface

- How the code fits together
 - interface btw programmers
 - interface btw parts of an app
- Given by specifications
 - Class spec and invariants
 - Method specs and preconds
 - Interface is ALL of these

Implementation

- What the code actually does
 - when create an object
 - when call a method
- Given by method **definitions**
 - Must meet specifications
 - Must not violate invariants
 - But otherwise flexible

Important concept for making large software systems

Implementing a Class

- All that remains is to fill in the methods. (All?!)
- When implementing methods:
 - 1. Assume preconditions are true
 - 2. Assume class invariant is true to start
 - 3. Ensure method specification is fulfilled
 - 4. Ensure class invariant is true when done
- Later, when **using the class**:
 - When calling methods, ensure preconditions are true
 - If attributes are altered, ensure class invariant is true

Recall: Enforce Preconditions with assert

```
def anglicize(n):
```

```
"""Returns: the anglicization of int n.
Precondition: n an int, 0 < n < 1,000,000"""
assert type(n) == int, str(n)+' is not an int'
assert 0 < n and n < 1000000 [repr(n)+' is out of range'
# Implement method here...
 Check (part of)
                               (Optional) Error message
                              when precondition violated
 the precondition
```

Enforce Method Preconditions with assert

class Time(object):

"""Class to represent times of day."""

```
def __init__(self, hour, min):
    """The time hour:min.
    Pre: hour in 0..23; min in 0..59"""
    assert type(hour) == int
    assert 0 <= hour and hour < 24
    assert type(min) == int
    assert 0 <= min and min < 60</pre>
```

```
def increment(self, hours, mins):
    """Move this time <hours> hours
    and <mins> minutes into the future.
    Pre: hours is int >= 0; mins in 0..59"""
    assert type(hour) == int
    assert type (min) == int
    assert hour >= 0
    assert 0 <= min and min < 60</pre>
```

Inv: hour is an int in 0..23 Inv: min is an int in 0..59"""

Initializer creates/initializes all of the instance attributes.

Asserts in initializer guarantee the initial values satisfy the invariant.

Asserts in other methods enforce the method preconditions.

Hiding Methods From Access

- Hidden methods
 - start with an underscore
 - do not show up in help()
 - are meant to be internal (e.g. helper methods)
- But they are **not restricted**
 - You can still access them
 - But this is bad practice!
 - Like a precond violation
- Can do same for attributes
 - Underscore makes it hidden
 - Only used inside of methods

class Time(object):
 """Class to represent times of day.

```
Inv: hour is an int in 0..23
Inv: min is an int in 0..59"""
```

```
def _is_minute(self,m):
    """Return: True if m valid minute""""
    return (type(m) == int and
        m >= 0 and m < 60)</pre>
```

def __init__(self, hour, min): """The time hour:min. Pre: hour in 0..23; min in 0..59""" assert self._is_minute(m)

Helper

Hiding Methods From Access

- Hidden methods
 - start with an underscore
 - do not show up in help()
 - are meant to be internal (e.g. helper methods)
- But they are **not restricted**
 - You can still access them
 - But this is bad practice!
 - Like a precond violation
- Can do same for attributes

class Time(object):

"""Class to represent times of day.

```
Inv: hour is an int in 0..23HIDDENmin is an int in 0..59"""
```

```
def _is_minute(self,m):
```

"""Return: True if m valid minute"""

return (type(m) == int and m >= 0 and m < 60)

def __init__(self, hour, min): """The time hour:min. Pre: hour in 0..23; min in 0..59""" assert self._is_minute(m)

Helper

Enforcing Invariants

class Time(object):

"""Class to repr times of day.

Inv: hour is an int in 0..23 Inv: min is an int in 0..59

> **Invariants**: Properties that are always true.

- These are just comments!
 >> t = Time(2,30)
 >> t.hour = 'Hello'
- How do we prevent this?

- Idea: Restrict direct access
 - Only access via methods
 - Use asserts to enforce them
 - Example: def getHour(self): """Returns: the hour""" return self.hour

def setHour (self,value):
 """Sets hour to value"""
 assert type(value) == int
 assert value >= 0 and value < 24
 self.numerator = value</pre>

Data Encapsulation

- Idea: Force the user to only use methods
- Do not allow direct access of attributes

Setter Method

- Used to change an attribute
- Replaces all assignment statements to the attribute
- Bad:

>>> t.hour = 5

• Good:

>>> t.setHour(5)

Getter Method

- Used to access an attribute
- Replaces all usage of attribute in an expression
- Bad:
 - >>> x = 3*t.hour
- Good:
 - >>> x = 3*t.getHour()

Data Encapsulation

class Time(object):

NO ATTRIBUTES

in class specification

Getter

Setter

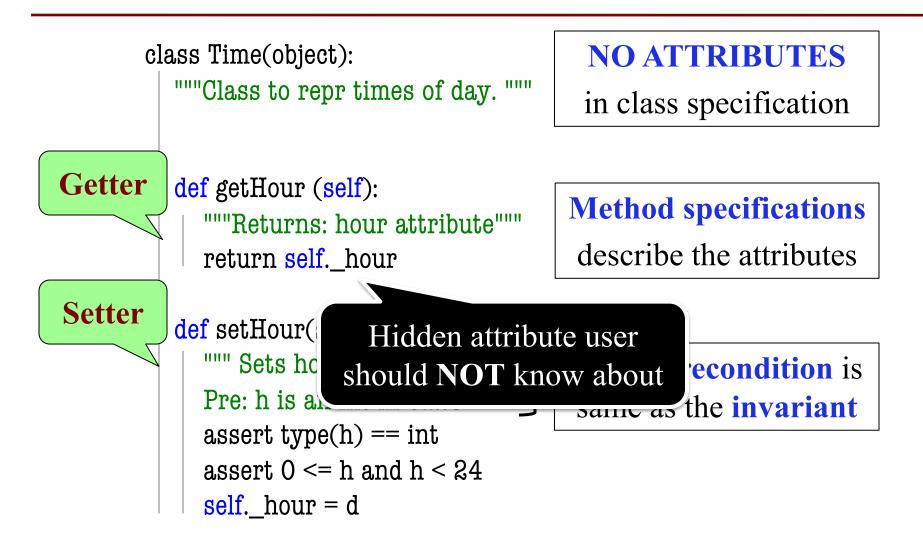

def getHour (self): | """Returns: hour attribute""" | return self._hour

Method specifications describe the attributes

def setHour(self, h):
 """ Sets hour to h
 Pre: h is an int in 0..23"""
 assert type(h) == int
 assert 0 <= h and h < 24
 self._hour = d</pre>

Setter precondition is same as the invariant

Data Encapsulation

Encapsulation and Specifications

"""Class to represent times of day. ### Hidden attributes # Att __hour: hour of the day # Inv: __hour is an int in 0..23 # Att __min: minute of the hour # Inv: __min is an int in 0..59

class Time(object):

No attributes in class spec

These comments make it part of the **class invariant** but not part of the (public) **interface**

These comments do not go in help()

Class Invariant vs Interface

Class Invariant

- List attributes that are present
 - Both hidden AND unhidden
 - Lists the invariants of each
- For the **implementer**
 - Guide for the initializer
 - Guide for method definitions

Interface

- Describes what is accessible
 - Unhidden methods/attribs
 - What is visible in help()
- For user/other programmers
 - Enough to create an object
 - Enough to call the methods

Early years of CS1110 confused these two topics

Mutable vs. Immutable Attributes

Mutable

- Can change value directly
 - If class invariant met
 - **Example:** turtle.color
- Has both getters and setters
 - Setters allow you to change
 - Enforce invariants w/ asserts

Immutable

- Can't change value directly
 - May change "behind scenes"
 - **Example:** turtle.x
- Has only a getter
 - No setter means no change
 - Getter allows limited access

May ask you to differentiate on the exam

Mutable vs. Immutable Attributes

Mutable

- Can change value directly
 - If class invariant met
 - **Example:** turtle.color
- Has both getters and setters
 - Setters allow
 - Enforce invar Next Thursday

Where?

Immutable

- Can't change value directly
 - May change "behind scenes"
 - **Example:** turtle.x
- Has only a getter
 - No setter means no change
 - Getter allows limited access

May ask you to differentiate on the exam
